

Bitmap Indexes.

11

- Assumption:

Records in a file have

a permanent number (position id) associated with each record.

eg: ~~file~~ record position

→ A specific field in the record.

- Field F = (domain?)

= Current set of values stored in a field F in the record.

- Bitmap index for the field F =

- a collection of bit vector of length n ($n = \#$ records in the file).

- One bit vector for each possible value V that appear in the field F.

- Bit vector for value V =

$x_i = 1$ if i th record's field $F = V$.

Example:

File has 6 records: (A,B)

1 (30, foo) 2 (30, bar) 3 (40, baz)
4 (50, foo) 5 (40, bar) 6 (30, baz)

record position.

Bitmap index for field A:

	1	2	3	4	5	6
30	1	1	0	0	0	1
40	0	0	1	0	1	0
50	0	0	0	1	0	0

Bitmap index for field B:

	1	2	3	4	5	6
foo	1	0	0	1	0	0
bar	0	1	0	0	1	0
baz	0	0	1	0	0	1

Example: gold-jewelry data.

Age Salary

1: (25, 60) 2: (45, 60) 3: (50, 75) 4: (50, 100)

5: (50, 120) 6: (70, 110) 7: (85, 140) 8: (30, 260)

9: (25, 400) 10: (45, 350) 11: (50, 275) 12: (60, 260)

Bitmap index on Age:

	1	2	3	4	5	6	7	8	9	10	11	12
25:	1	0	0	0	0	0	0	0	1	0	0	0
30:	0	0	0	0	0	0	0	1	0	0	0	0
45:	0	1	0	0	0	0	0	0	0	1	0	0
50:	0	0	1	1	1	0	0	0	0	0	1	0

	1	2	3	4	5	6	7	8	9	10	11	12
60:	0	0	0	0	0	0	0	0	0	0	0	1
70:	0	0	0	0	0	1	0	0	0	0	0	0
85:	0	0	0	0	0	0	1	0	0	0	0	0

Bitmap index on Salary:

	1	2	3	4	5	6	7	8	9	10	11	12
60:	1	1	0	0	0	0	0	0	0	0	0	0
75:	0	0	1	0	0	0	0	0	0	0	0	0
100:	0	0	0	1	0	0	0	0	0	0	0	0
110:	0	0	0	0	0	1	0	0	0	0	0	0
120:	0	0	0	0	1	0	0	0	0	0	0	0

	1	2	3	4	5	6	7	8	9	10	11	12
140:	0	0	0	0	0	0	1	0	0	0	0	0
260:	0	0	0	0	0	0	0	1	0	0	0	1
275:	0	0	0	0	0	0	0	0	0	0	1	0
350:	0	0	0	0	0	0	0	0	0	1	0	0
400:	0	0	0	0	0	0	0	0	1	0	0	0

Example using bit map index:

Find buyer (ot jewelry) with:

[age = 50
Salary = 100.

Bitmap index for age = 50 : 001110000000
Bitmap index for Salary = 100 : 000010000000

AND 000010000000

✓
The 5th record satisfies
all criteria.

(50, 120).

• Strength of Bitmap Indexes:

1 Can answer partial match queries efficiently.

Eg:

Find buyers (of jewelry) with

age = 50.

Use bitmap index for

age = 50: 1 2 3 4 5 6 7 8 9 10 11 12
 0 0 1 1 1 0 0 0 0 0 0 0

 ↘ records 3, 4, 5

2 Can answer range queries efficiently.

Eg: Find buyers (of jewelry) with:

$45 \leq \text{age} \leq 55$
 $100 \leq \text{salary} \leq 200$

range query.

Solution:

$45 \leq \text{age} \leq 55$ has these values:

		1	2	3	4	5	6	7	8	9	0	12
age = 45	:	0	1	0	0	0	0	0	0	0	1	00
age = 50	:	0	0	1	1	1	0	0	0	0	0	10

0 1 1 1 1 0 0 0 0 1 1 0

OK

$100 \leq \text{salary} \leq 200$ has these values:

		1	2	3	4	5	6	7	8	9	0	12
sal = 100	:	0	0	0	1	0	0	0	0	0	0	00
sal = 110	:	0	0	0	0	0	1	0	0	0	0	00
sal = 120	:	0	0	0	0	1	0	0	0	0	0	00
sal = 140	:	0	0	0	0	0	1	0	0	0	0	00

0 0 0 1 1 1 1 0 0 0 0 0

OK

$(45 \leq \text{age} \leq 55) \text{ AND } (100 \leq \text{salary} \leq 200)$

has as solution.

AND

	1	2	3	4	5	6	7	8	9	0	12
	0	1	1	1	1	0	0	0	0	1	10
	0	0	0	1	1	1	1	0	0	0	00
	0	0	0	1	1	0	0	0	0	0	00

rewards 4, 5

Storing Bitmap Indexes:

- Naïve way to store bitmap indexes is very inefficient:

Suppose: field F (file has n records)
↓
m different values:

$$\begin{array}{l} V_1 = x x x x x \dots \\ V_2 = x x \dots \dots \dots \\ \vdots \\ V_m = x x \dots \dots \dots \end{array} \quad \left. \vphantom{\begin{array}{l} V_1 \\ V_2 \\ \vdots \\ V_m \end{array}} \right\} \begin{array}{l} m \cdot n \text{ bits} \\ \text{total.} \end{array}$$

$\underbrace{\hspace{10em}}_{n \text{ bits}}$

• Note:

$$\begin{array}{l} V_1 = \\ V_2 = \\ \vdots \\ V_m = \end{array} \left[\begin{array}{l} x x x x \dots \\ x x x x \dots \\ \vdots \\ x x x \dots x \end{array} \right]$$

$\underbrace{\hspace{10em}}_{\emptyset}$

$$\text{total \# 1-bits} = n.$$

$$\text{total \# 0-bits} = m \cdot n - n$$

$$= (m-1) \cdot n.$$

(If m is large, you will have a lot of 0-bits !!!) $\rightarrow$ compression !!!

Compressed Bitmaps

- Observation: $m = \#$ possible values in a field F .

When m is large:

$$\begin{cases} V_1 = 00 \dots 1000 \dots 1000 \dots \\ V_2 = \\ \vdots \\ V_m \end{cases}$$

Many 0 bits

there will be many 0's in the bit vectors !!!

- Definition: Run

Run = a sequence of 0 bits followed by one (single) 1 bit.

eg: 1 run length = 0
 01 run length = 1
 00001 run length = 4.

- Run length = # 0 bits in the run.

- Run length encoding = representation of a bit vector by the run lengths.

eg: $n = 20$ (20 bits in bit vector)

bit vector: 00010000010010000000

20 bits

3 5 2

not encoded

runlength encoding = 3 5 2

Fact:

- Run length encoding is done in binary.

So:

00010000010010000000

3 5 2

↓

11 101 10

- \$64,000 question:

How do we encode the run lengths ???

How to represent the run length code in binary:

Fact: you cannot ~~simply~~ represent each run length as a binary number and simply concatenate the bits.

Example:

bit vector 1:

000101

3 1

=11 =1

$\Rightarrow$ code = 111

bit vector 2:

010101

1 1 1

$\Rightarrow$ code = 111

Ambriguous!!!

Run length encoding:

Run length = same binary number of k digits

Encoding:

11110

k bits.

runlength in binary

Example:

$$\begin{matrix} 8 & +4 & +1 & = & 13. \\ (& (& / \end{matrix}$$

run length = 13

binary = 1101

Encoding:

11101101

Next 4 digits
is the run length

13

Example Encoding:

bit vector:

$n = 20.$
00010000010010000000

3

5

2

Not coded

11

11

11

11

101

10.

1011101011010

↓ Decode

11 101 10

↓ ↓ ↓

3 5 2.

(you need to remember $n=20$ explicitly).

Analysis: # bits used in bit map index.

Previously : (uncompressed).

$$\left. \begin{array}{l} V_1 = \text{---} \xrightarrow{n \text{ bits}} \text{---} \\ V_2 = \text{---} \text{---} \text{---} \text{---} \\ \vdots \\ V_m = \text{---} \end{array} \right\} \# \text{ bits} = m \times n.$$

Suppose $m = n$ (Every value occurs only once)
best case compression
worst case size for
bit map.

$$\text{uncompressed} = n^2 \text{ bits.}$$

Compressed:

$$\begin{array}{l} V_1 = \text{---} \text{---} \text{---} 1 \text{---} \text{---} \\ V_2 = \text{---} \text{---} \text{---} \text{---} 1 \text{---} \end{array}$$

$$\uparrow \text{avg } \# \text{ } 1 = \frac{1}{2}n \cdot \approx n.$$

Needs $\lg(n)$ bits

to repr. ~~diff~~ number n .

Code for 1 bit vector: $\underbrace{111110}_{\lg(n) \text{ bits}}, \underbrace{\hspace{1cm}}_{\lg(n) \text{ bits}}$

$$= 2 \lg(n) \text{ bits.}$$

$$\begin{array}{l}
 v_1 = \dots \\
 v_2 = \dots \\
 \vdots \\
 v_{m=n} = \dots
 \end{array}
 \left. \begin{array}{c}
 \text{ } \\
 \text{ } \\
 \text{ } \\
 \text{ } \\
 \text{ }
 \end{array} \right\} \begin{array}{c}
 2 \lg(n) \text{ bits} \\
 \\
 \\
 \\
 \\
 \end{array} n.$$

$$\text{Total \# bits} = \underline{\underline{2n \lg(n)}} \text{ bits}$$

$$\underline{\underline{(\text{vs. } n^2 \text{ \# bits})}} !!!$$

Operations on Run-length encoded Bit-vectors:

- There is over head involved to perform operations on Run-length encoded Bit vectors:

Run-length encoded bit vector

(1) ↓ Decode.

Bit vector

(2) ↓ Perform desired operation.

- Trick:
"Just-in-time" decoding.

Example: OR on these encoded bitvectors:

vector 1: 00110111 (n=12)
vector 2: 110111

Naive: decode and then perform OR

=> 100000000 | 000

0000000010000

Then perform (OR) operation:

OR

100000000 | 000
000000001 | 0000
100000001 | 000

Answer.

Just-in Time decoding:

Vector 1: 0 0 1 1 0 1 1 1

Vector 2: 1 1 0 1 1 1

1
0 0 0 0 0 0 0 1
OR
1

decode vector 1
further.

0 0 1 1 0 1 1 1

1 0 0 0 0 0 0 1

0 0 0 0 0 0 1

1 0 0 0 0 0 1

Decode
vector 2
further.

Managing Bitmaps Indexes.

- Storing Bitmap Indexes:

- Use an index file on the values in the field.
- Schematically:

- Retrieving records using bit map index.

but vector = $\dots$ $\downarrow$ position vec

- Use ~~the~~ Secondary Index to index the records on their position.

- Maintaining bitvector when records are: inserted and deleted.

Problem: record numbers must remain FIXED once it is assigned to a record!

- Delete a record i

(1) Replace record i with a tombstone
(retire the record number!)

(2) Bit vector for V_k :

- Insert a new record

Field F has value V_k .

Old values:

	n	$n+1$
$V_1 =$	...	$\emptyset$
$V_2 =$	...	$\emptyset$
$V_k =$	...	1
$V_m =$	...	$\emptyset$

old values

new value.

update this bit vector.

- We only need to re-code the Run-length code for

$$V_k = \dots 1$$

(The other run-length codes remain unchanged!!!).

- If V_k is a new value, add:

$$V_k = .000 \dots 0 1.$$

Update a value :

(1) Update 2 bit vectors:
